Agoudal meteorite

 Agoudal iron meteorite Centre- south morocco	**Characteristics:** Agoudal meteorite is an iron meteorite of the rare IIAB group, is composed mainly of iron with about 5–6% nickel & contains inclusions such as schreibersite and troilite.Its fragments are dense, metallic & often show Neumann lines. **Natural occurrences:** It naturally occurs as scattered masses in the remote Atacama Desert of northern Chile. Its pieces are found across a strewn field spanning up to 8 kilometers, suggesting a large parent body exploded in the atmosphere before impact. The arid climate preserves these pallasite fragments, often leaving skeleton-like iron frameworks as surface olivine weathers away. **Fun facts:** It marks a rare impact site with shatter cones, offering unique scientific insights into meteorite impacts and Earth's geology.
