CHALCOPYRITE

 Chalcopyrite is a brass-yellow mineral with the formula $CuFeS_2$	**Characteristics:** high specific gravity, brassy color, and metallic luster resemble both pyrite and gold, though it can be distinguished by its brittleness, greenish-gray streak, and softness—it scratches easily with a nail, unlike harder pyrite. **Natural Occurrence:** Found in many sulfide deposits worldwide. It may crystallize from igneous melts, form by magmatic segregation in layered rocks, or, most commonly, appear in hydrothermal veins and as replacements in country rock. **Fun facts:** Despite chalcopyrite being mainly used as a copper ore this use should not be understated. It has been the primary ore of copper since smelting begun 5000 years ago and to this day is still the primary ore of copper.
