FOSSILIFEROUS LIMESTONE

  Fossiliferous limestone is a sedimentary rock rich in fossils.	**Characteristics:** Fossiliferous limestone is a type of limestone that contains noticeable quantities of fossils or fossil traces. If a particular type of fossil dominates, a more specialized term can be used as in "Crinoidal", "Coralline", "Conchoidal" limestone. **Natural Occurrences:** Fossiliferous limestone is formed by the accumulation and compression of organic remains—such as shells, coral, and other marine organisms—mixed with sediment. **Fun facts:** Fossiliferous limestone holds paleontological value, preserving records of species evolution, biodiversity, and ancient ecosystems. Its fossils reveal past environmental conditions, indicating marine or freshwater settings.
